The array may contain several points, so finding the closest to the

one with the smallest distance is not the solution here. I am looking for a solution that, given a point, finds the closest point in the array and returns the closest distance from the point in the array. I am working with 3D points, but a general solution will be useful for other kind of points. I have already written a solution, but I am not confident that it is the most optimal solution in terms of number of function calls. A: First, let's have a function to return a list of all the points closer than the given point. You do not say anything about what happens if no point is closer than the given point. Therefore, I assume that you just return the given point itself, as no point is better than the given point. EDIT: To return only points closer than the given point, you can use SortBy: Let's say we have the points in a list: points = RandomInteger[{-1, 1}, {5, 3}] {{ -0.307977, -0.853123, 0.367183}, {0.158893, 0.269836, -0.554046}, {0.443871, -0.280357, 0.82157476af
